Exam 1 Review - CS 2124, Fall 2023

Disclaimer: This mock exam is only for practice. It was made by tutors in the Polytechnic Tutoring Center and is not representative of the actual exam given by the CS Department.

- 1. Declare:
 - a. An unchanging pointer to an int
 - b. A pointer to an unchanging int
 - c. An unchanging pointer to an unchanging int
- 2. What will the following code result in?

```
int main(){
    int i = 7;
    const int* ip = &i;
    i += 1;
    cout << i << endl;
}</pre>
```

- a. 7
- b. 8
- c. Runtime error
- d. Compilation error
- 3. What will the following code result in?

```
int main(){
        const int i = 7; //line A
        int* ip = &i; //line B
        cout << i << endl; //line C
}</pre>
```

- a. It will just print out 7
- b. It will have an error at line A
- c. It will have an error at line B
- d. It will have an error at line C
- e. The program will crash
- f. It is undefined

4. What will the following code result in?

```
int* foo(int x) {
    int y = 2*x;
    int* p = &y;
    return p;
}
int main() {
    int z = 29;
    cout << *foo(z);
}</pre>
```

- a. Compilation error
- b. Segmentation fault error
- c. Runtime error
- d. The program will crash
- e. It is undefined
- 5. Given the struct defined below, what would be the result of:

```
struct CovidStatus {
    int infected;
    int victims;
    int recovered;
private:
        CovidStatus();
};
int main() {
        CovidStatus covid19;
        cout << covid19.infected << endl;
}</pre>
```

- a. Runtime error
- b. Compilation error
- c. It is undefined
- d. None of the above

6. Given that there is a class Thing that has an attribute called item, and tp is a pointer to a Thing, what is the meaning of the following?

```
tp->item

a. *(tp.item)
b. (tp.item)*
c. *tp(.item)
d. (*tp).item
```

7. Given the struct definition below, write a function that iterates over a vector of Account objects and finds the Account object with a specified acc_id. The function should pass in the vector of Account objects as well as the acc_id, and then return the index of the matching Account. If you do not find the Account with the specified acc_id, simply return a reasonable value.

```
struct Account {
    int acc_id;
    int balance;
}
```

8.	Using the struct definition in question 7 for Account. Create a function that reads through a file
	and uses the contents of the file to modify an array that holds a maximum capacity of say 10
	pointers to Account objects. The contents of the file would be similar to that seen below:

ID: 89203482 Balance: 124

ID: 09859403
Balance: 877

ID: 71934098 Balance: 1080

The output from the function, when called on this particular file, would yield an array of three pointers to Account objects each with the acc_id and balance attributes as seen above. Note that the function should not return the array itself, rather it should pass in the array and add the pointers to it.

9. Write a program that then iterates over this array of Account pointers and frees up all the memory within the array, including the array itself.

- 11. Write a class Employee to model the employees in a company PolyCo.
 - In PolyCo, each employee has a name, can have only one boss and zero or more subemployees.
 - The CEO of PolyCo doesn't have a boss, of course, but every other employee does.
 - When employees are created, there are the following two possibilities:
 - They can be told who their boss is right away.
 - They can be created without a boss.
 - Every Employee is also a boss
 - Employees should be able to be added and removed from the list of sub-employees at any time in the future. Provide support for this. Think about the fact that employees in the team need to know who their boss is, and the boss needs to know who's in his team.
 - Important: Only write the class Employee!
 - Assume that there will be no duplicate employees added to a boss employee.
 - Since employees can have only one boss, if we hire someone who already has a boss, we should not let this happen and report a failure.
 - Here's a sample main and the sample output it produces, make sure your code, if ran, will have the same output as seen here.
 - Make sure you write an output operator for the Employee class.
 - Note: This problem does not involve copy control or the heap

```
int main()
{
        Employee sterling("Professor Sterling");
        Employee yan("Yan", &sterling);
        Employee jeremy("Jeremy");
        Employee mike("Mike");
        yan.addToTeam(jeremy);
        yan.addToTeam(mike);
        cout << yan << endl;
        cout << sterling << endl;
}
Output:

Name: Yan
Boss: Professor Sterling
Team...
        Jeremy
        Mike</pre>
```

12. Consider a simple class named Book that has a title stored as a dynamically allocated string

Implement the constructor that takes a string and sets the Book's title to this string. Implement the copy constructor to ensure a deep copy of the title. Implement the copy assignment operator to ensure a deep copy of the title. Implement the destructor to free any dynamically allocated memory.
